Comments & Signature (Dr Manoj)

Declaration of Originality

We, hereby declare that this report entitled **“Restruct AI: A scalable algorithmic intelligence for data extraction and knowledge structuring"** represents our original work carried out for the Capstone project as a student of VIT Bhopal University and, to the best of our knowledge, it contains no material previously published or written by another person, nor any material presented for the award of any other degree or diploma of VIT Bhopal University or any other institution. Works of other authors cited in this report have been duly acknowledged under the section "References".

Date: 20th March, 2026

Reg no. & Name

1. 22BEY1007 Shreshth Katyayan
2. 22BEY10022 Ishaan Mishra
3. 22BEY10025 Antrika Kashyap
4. 22BEY10051 Vaishak Unnithan
5. 22BEY10063 Ishita Bairagi

Acknowledgement

We would like to express our heartfelt gratitude to everyone who contributed to the development of our CAPSTONE project, RestructAI: An Algorithmic Intelligence for Data Extraction and Knowledge Structuring. This project represents our collective effort to address critical limitations in modern Document Intelligence systems by integrating multimodal extraction, spatial grounding, knowledge graph modeling, and self-verification mechanisms to enable reliable and enterprise-ready structured outputs.

We extend our deepest thanks to our supervisor, Dr. Satyabrata Nath, for his unwavering support, insightful guidance, and invaluable feedback throughout this project. His expertise has been instrumental in helping us shape our ideas and execute them effectively. Our heartfelt appreciation goes to VIT Bhopal University for providing us with an excellent platform and resources to explore and work on innovative ideas. The collaborative environment and emphasis on experiential learning have been pivotal in driving our progress.

Finally, we acknowledge the contribution of our team members, whose dedication, enthusiasm, and hard work have been the cornerstone of this project. Their collaborative efforts in preparing the deep learning model and gathering the initial data have laid a strong foundation for further development. As we present our progress in this second review, we look forward to feedback and guidance to improve and complete our project successfully. Thank you for your support and encouragement in our journey toward creating safer roads through technology.

Abstract

Enterprises today rely heavily on automated systems to extract information from documents such as financial reports, legal contracts, research papers, and technical manuals. However, most existing Document AI tools still struggle with complex layouts, multi-page documents, and elements like tables and figures. These systems often fail to preserve the original structure, misinterpret tabular data, and generate outputs that cannot be easily verified or traced back to their source. As a result, many organizations hesitate to fully trust these systems, especially in areas where accuracy and accountability are critical.

To address these challenges, RESTRUCT AI- Scalable Algorithmic Intelligence for Data Extraction and Knowledge Structuring has been developed as a modular and flexible Document Intelligence Framework. Unlike traditional systems that rely on predefined templates, RESTRUCT AI follows a structured pipeline grounded in three core principles: Perception, Reasoning, and Verification.

The system employs a multi-service backend architecture built around Flask (API Gateway), Celery (task orchestration), RabbitMQ (message brokering), Redis (caching and status events), MinIO (document storage via S3-compatible interface), and a GPU/CUDA-accelerated Vision Engine. A RAG Orchestrator manages the retrieval-augmented generation pipeline, while a Reasoning Engine powered by Large Language Models enables semantic schema mapping and contextual understanding. A Graph Manager employs a multi-stage Document Graph Model— incorporating Sparse Graph Construction, Hierarchical Node Expansion, Edge Prediction via MLP, Local Attention for component-level understanding, and Global Attention for cross-element and cross-page reasoning— to maintain the Knowledge Graph, enabling cross-page entity linking and structured knowledge representation. All outputs are stored in a dedicated Embedding Store for fast retrieval.

Overall, RESTRUCT AI stands out for its flexibility, accuracy, and scalability. By reducing errors and ensuring traceability, it transforms unstructured documents into structured and trustworthy data. This makes it a practical and reliable solution for modern enterprise needs, moving beyond traditional OCR systems toward more advanced and dependable Document Intelligence.

1. INTRODUCTION

In today's enterprise world, organizations deal with a huge number of complex documents such as financial reports, legal contracts, research papers, compliance records, and technical manuals. Extracting meaningful and structured information from these documents is still a major challenge. Traditional OCR systems usually convert everything into plain text, which removes the original layout, misinterprets tables, and ignores visual elements like charts or figures. Even newer AI-based Document Intelligence tools are not fully reliable, as they can produce outputs that are difficult to verify, structurally inconsistent, and sometimes incorrect, which raises concerns about accuracy and trust.

Another important limitation of existing systems is their reliance on predefined templates. Whenever the required output format changes, these systems often need retraining or manual adjustments. They also struggle to maintain context across multiple pages and lack strong mechanisms to trace extracted information back to its original source.

To overcome these issues, RESTRUCT AI has been developed as a template free, modular, and scalable Document Intelligence system. Rather than relying on fixed schemas, RESTRUCT AI follows a structured, three-layer approach grounded in Perception (layout-aware extraction), Reasoning (LLM-based schema alignment and contextual linking), and Verification (bounding-box anchored self-validation). The system is architected around a cloud-native microservices stack that allows independent scaling of its constituent components.

The core backend infrastructure—illustrated in the architecture diagram—integrates an API Gateway built with Flask and SocketIO, an asynchronous Ingestion Service powered by Celery, message brokering via RabbitMQ (with dedicated queues for ingestion, vision, and graph tasks), a GPU/CUD Accelerated Vision Engine, a Graph Manager for knowledge graph operations, a RAG Orchestrator for retrieval-augmented query handling, a Reasoning Engine (LLM), an S3-compatible document store via MinIO with nginx as proxy, Redis for caching and event streaming, and a dedicated Embedding Store. Real-time communication with browser clients is handled through WebSocket connections, enabling live status updates. RESTRUCT AI is designed to convert unstructured documents into structured, reliable, and auditable data. It represents a practical and scalable approach to Document Intelligence— prioritizing adaptability, accuracy, and trust for real-world enterprise deployments.

1.1 Motivation

The idea behind RESTRUCT AI came from real-world experience with existing document automation tools. While many of these tools claim high accuracy, they often struggle when dealing with complex, multi-page documents that include tables, charts, references, and mixed content. These limitations are not just technical issues—they can directly affect important decisions in areas like finance, legal work, research, and governance.

1.1.1 Challenges in Handling Complex Documents

Modern enterprise documents are much more than simple text. They often contain structured tables, diagrams, multi-column layouts, and references spread across different pages. Most current systems simplify this structure into plain text, losing important relationships between different elements. For example, a footnote explaining a value on another page may be completely ignored, leading to incomplete understanding.

1.1.2 Accuracy and Trust Issues

In enterprise use cases, accuracy is extremely important. Even a small mistake in a financial figure or legal clause can have serious consequences. However, many existing systems do not provide a clear way to trace extracted data back to its original source in the document. This lack of traceability makes it difficult to verify results and reduces trust in the system.

1.1.3 Hallucination in AI Outputs

AI-based systems, especially those using language models, can sometimes generate information that looks correct but is not actually present in the document. This becomes risky when dealing with technical or numerical data. Without proper validation, such errors can go unnoticed, making reliable verification essential.

1.1.4 Lack of Flexibility

Most document processing tools depend on fixed templates. Whenever the output format changes, they require retraining or manual adjustments. This makes them less flexible and increases both time and cost, especially in dynamic environments where requirements keep evolving.

1.1.5 Need for Structured Data at Scale

Organizations rely heavily on structured data for analysis and decision-making. However, a large amount of important information is still stored in unstructured documents. There is a strong need for systems that can convert these documents into structured and usable data efficiently and at scale.

RESTRUCT AI was developed to directly address these challenges. Its design focuses on combining efficient processing, structured representation, and verification to handle real-world document complexity in a reliable way.

1.2 Objectives

The main goal of RESTRUCT AI is to improve accuracy, flexibility, scalability, and reliability in document processing. Instead of just improving existing systems, it aims to provide a more complete and practical solution for real world use.

1.2.1 Template-Free Extraction

The system is designed to handle different types of document content such as text, tables, and visual elements without relying on predefined templates. It preserves the original structure and relationships within the document during extraction.

1.2.2 Dynamic Schema Mapping (Zero-Shot)

RESTRUCT AI allows extracted data to be mapped into different output formats without retraining. This makes the system flexible and adaptable to changing requirements.

1.2.3 Traceability through Spatial Grounding

Each extracted value is linked to its exact position in the document. This makes it easy to verify results and ensures transparency.

1.2.4 Reducing Errors through Verification

A verification layer checks extracted data before final output, helping reduce incorrect or inconsistent results.

1.2.5 Knowledge Graph for Better Understanding

The system uses a Knowledge Graph to connect related information across different parts of the document, improving context understanding and relationships.

1.2.6 Scalable System Architecture

RESTRUCT AI is built using a microservices-based architecture with components like API gateway, task workers, message queues, storage systems, and processing engines. This allows the system to scale easily and handle large workloads efficiently.

1.2.7 Real-Time Communication

The system supports real-time updates using WebSockets, allowing users to track processing progress and interact with the system smoothly.

Future Scope and Enterprise Integration

The long-term vision is to integrate RESTRUCTAI with enterprise systems such as databases, analytics platforms, and compliance tools. This will help convert unstructured documents into structured, usable knowledge that organizations can easily work with.

2. EXISTING WORK / LITERATURE REVIEW

2.1. Introduction

Document Intelligence has become increasingly important as organizations rely more on automated systems to handle large volumes of diverse documents. These documents often include a combination of text, tables, images, and references spread across multiple pages, making accurate and structured extraction a challenging task. The introduction of powerful language models like BERT marked a major shift in how machines understand text, enabling better performance through large-scale pre-training and fine-tuning. Building on this progress, newer multimodal approaches have been developed to process not just text, but also layout and visual information together, improving results in tasks like form and receipt analysis.

Despite these advancements, current systems still face several limitations. Many struggle to preserve document structure, ensure reliable outputs, scale effectively, or operate efficiently in real-time scenarios. This section reviews the existing work related to document processing, highlights the gaps in current approaches, and explains how RESTRUCT AI is positioned to address these challenges with a more structured and reliable solution.

2.2. Traditional Document Processing Methods

Early document processing systems mainly depended on Optical Character Recognition (OCR) tools like Tesseract, which convert images of documents into text using steps such as image preprocessing, layout detection, and character recognition. These tools work well for simple documents with a straightforward layout, but they struggle when dealing with more complex formats. The main issue is that they do not understand document structure. Instead, they convert everything into a linear stream of text, ignoring important spatial relationships between elements like tables, headings, figures, and columns.

Because of this, key details such as positioning, formatting, and layout—which often carry important meaning in documents like financial reports or legal contracts—are lost during processing. As a result, tables become difficult to reconstruct and references across sections or pages are often missed. Later tools like PaddleOCR improved text recognition accuracy and added support for multiple languages, but they still do not fully solve the problem of structural understanding. While OCR remains an important first step in document processing, its output alone is not sufficient for building reliable, enterprise level Document Intelligence systems without additional processing and interpretation layers.

2.3. Layout-Aware Document Models

The introduction of models like LayoutLM marked an important step forward in document understanding. Unlike traditional approaches, LayoutLM combines text with its spatial position on the page, allowing the model to better capture the structure of documents. By integrating layout information directly into the learning process, it showed clear improvements in tasks like form and receipt understanding, where both content and placement matter. This was one of the first approaches to treat text and layout together within a single framework instead of relying on separate processing steps.

Building on this, LayoutLMv3 further improved the approach by combining text and image information in a unified model. It introduced techniques to better align text with visual elements

in the document, leading to strong performance across a range of tasks such as document question answering and layout analysis. However, despite these advancements, both models still have limitations. They typically require labelled data and task-specific training, which reduces their flexibility when dealing with new formats. In addition, they do not provide strong mechanisms for tracing outputs back to their source or verifying results, which are essential for reliable, real-world applications.

2.4. Table Extraction Techniques

Table extraction from PDF documents has traditionally been handled using rule-based tools like Camelot and Tabula. These tools work by analyzing the layout of a document— either by detecting table borders or by identifying patterns in the spacing between text elements. They perform well when tables are neatly structured, with clear lines and consistent formatting.

However, in real-world scenarios, tables are often much more complex. They may include merged cells, uneven columns, missing borders, or even span across multiple pages. In such cases, these tools tend to struggle and may produce incorrect or incomplete outputs. For example, when tables do not have clear borders, the system relies only on spacing, which can easily lead to misaligned columns or missing data. Another important limitation is that these tools work independently and do not consider the broader document context. They cannot link table data to surrounding text, handle cross-page tables properly, or trace extracted values back to their exact position in the original document. In enterprise settings, where accuracy and verification are critical, these limitations make rule-based table extraction methods less reliable without additional processing or validation layers.

2.5. Vision-Language Models (VLMs)

Another important area of research focuses on using Vision-Language Models (VLMs) for document understanding. These models process documents directly as images, removing the need for a separate OCR step. One well-known example is Donut, which

uses a transformer-based architecture to read and understand documents from raw image inputs. It combines an image encoder with a text decoder that generates structured outputs, such as JSON, making it possible to extract information in an end-to-end manner. This approach has shown strong performance across different types of documents and reduces processing time by avoiding OCR altogether.

However, despite these advantages, VLM-based approaches still have several limitations. Since the model processes the entire page as an image, it does not maintain explicit information about the exact location of each element, making it difficult to trace outputs back to their original positions. Handling large, multi-page documents can also become computationally expensive. Most importantly, these models can sometimes generate incorrect information that appears valid, especially when dealing with numbers or technical data. Without a proper verification mechanism, it becomes difficult to detect such errors, which limits their reliability in enterprise applications.

2.6. Retrieval-Augmented Generation (RAG)

Retrieval-Augmented Generation (RAG) is an important approach that combines language models with external data retrieval to improve the accuracy of generated responses. Instead of relying only on what the model has learned during training, RAG retrieves relevant information from a database and uses it to generate answers. This helps reduce incorrect outputs and allows the system to work with more up-to-date information. However, the standard RAG approach retrieves small chunks of text based on similarity, without considering how that information is structured within the document.

This becomes a problem when dealing with complex enterprise documents that include tables, cross-references, and multi-level sections. Since RAG treats documents as independent text chunks, it often loses important relationships between different parts of the document, leading to incomplete or out-of-context answers. To address this, newer approaches like Graph RAG use graph-based representations to better capture relationships between different pieces of information. This improves performance, especially for tasks that require understanding connections across the entire document. However, even these approaches are not specifically designed for structured document extraction. They do not fully handle aspects like spatial traceability or linking extracted data back to its exact position in the original document, which are essential for reliable enterprise applications.

2.7. Knowledge Graph Integration

Knowledge Graphs are widely used to represent information in a structured way by connecting entities and their relationships. They make it easier to perform tasks like searching, linking related data, and understanding connections across large datasets. Research in this area has shown that knowledge graphs are useful in many applications, including enterprise data management, semantic search, and question answering systems. In the context of document processing, they help organize extracted information into a format that can be easily queried and understood.

However, in most existing systems, knowledge graphs are built only after the data has already been extracted from documents. This creates a major limitation—if there are errors during extraction, such as missing values or incorrect relationships, those errors get carried forward into the graph without any correction. Additionally, many approaches do not include spatial information, such as the exact location of data within the document. This makes it difficult to trace extracted values back to their source, which is important for verification and auditing. As a result, the potential of knowledge graphs to improve accuracy and provide better validation during document processing is still not fully utilized in current systems.

2.8 Hallucination and Verification

One of the biggest challenges in using large language models for document processing is the issue of hallucination. While these models are very powerful and can understand and generate language effectively, they sometimes produce information that is incorrect or not actually present in the source document. In enterprise settings, this is a serious concern. Even a small mistake—such as an incorrect financial value, a wrong legal clause, or a misrepresented data point—can lead to significant consequences. This problem becomes even more critical when dealing with numbers, dates, or important entities, where accuracy is essential.

Approaches like Retrieval-Augmented Generation (RAG) help reduce this issue by allowing the model to refer to external information while generating responses. However, this does not completely solve the problem. If the retrieved data is incomplete or not directly relevant, the model may still generate incorrect or mixed information. Some methods try to verify outputs by linking them back to source text, but they usually work at a broader level and do not provide exact location-based validation within the document. Similarly, using knowledge graphs to check consistency has been explored, but it is not widely used in real-world systems. Overall, the lack of a strong verification mechanism that connects each output directly to its original source remains one of the main challenges in building reliable Document AI systems.

2.9. Scalable System Architectures

Modern document processing systems in enterprises are increasingly moving towards microservices-based architectures to improve scalability and reliability. Instead of building everything as a single large system, the workflow is divided into smaller, independent services that can be deployed and scaled separately. Tools like Docker and Kubernetes help manage these services efficiently, while message queues such as RabbitMQ or Kafka allow different components to communicate asynchronously. This makes it possible to handle tasks like document ingestion, processing, and analysis in parallel, improving overall performance.

Other supporting technologies also play an important role in building such systems. Object storage solutions like MinIO help manage large document files separately from the processing logic, while GPU acceleration improves the speed of computationally heavy tasks like vision processing. Redis is often used for fast data access and real-time updates, and vector databases enable quick retrieval of relevant information from large datasets. However, despite the availability of these technologies, most existing systems do not combine them into a single unified solution. Typically, systems focus either on scalability or on accuracy, but not both together. This creates a gap in building a complete, reliable, and scalable Document Intelligence platform that can handle real world enterprise requirements effectively.

2.10. Research Gap

Based on the analysis of existing research and systems, several important gaps can be identified. Most current solutions struggle to maintain the original layout and structure of complex, multi-page documents. They also have difficulty handling complex tables, irregular formats, and embedded visual elements. Another major limitation is their reliance on predefined templates, which makes them less flexible and requires retraining whenever the output format changes. In addition, many systems lack proper mechanisms to trace extracted data back to its exact source, making verification difficult.

There are also challenges related to accuracy and understanding. Existing approaches often do not handle hallucination effectively in AI-based extraction, and they struggle to maintain context across multiple pages. Moreover, there is no single system that brings together scalability, multimodal extraction, structured reasoning, and verification in one unified framework. RESTRUCT AI has been designed specifically to address these gaps through an integrated and multi-layered architecture.

2.11 Comparative Summary of Existing Approaches

Table 1 below synthesizes the key capabilities and limitations of the approaches reviewed in this chapter along four dimensions directly relevant to enterprise Document Intelligence: layout awareness, template independence, hallucination control, and the primary limiting factor. RESTRUCT AI is positioned against each prior work to illustrate the specific gaps it addresses. The table confirms that no single prior system simultaneously achieves layout aware extraction, template-free zero-shot schema mapping, and spatially-anchored hallucination control within a scalable production architecture.

Approach / System	Layout Aware	Template Free	Hallucination Control	Key Limitation
Tesseract OCR (Smith, 2007) [21]	No	Yes	None	No structural understanding; linearises layout
LayoutLM (Xu et al., 2020) [1]	Yes	No	None	Requires supervised fine-tuning; no traceability
LayoutLMv2 (Xu et al., 2021) [22]	Yes	No	None	Task-specific training; no zero-shot schema mapping
LayoutLMv3 (Huang et al., 2022) [2]	Yes	No	None	Fine-tuning dependent; no verification layer
Donut (Kim et al., 2022) [5]	Partial	Yes	Weak	No spatial anchoring; hallucination on numerics
Camelot / Tabula [8,9]	Partial	Yes	None	Fails on complex tables; no reasoning pipeline
Standard RAG (Lewis et al., 2020) [11]	No	Yes	Partial	Flat-chunk retrieval; loses document hierarchy
GraphRAG (Edge et al., 2024) [12]	No	Yes	Partial	General QA only; no structured extraction or traceability
RESTRUCT AI (This Work)	**Yes**	**Yes**	**Full (Bounding-box anchored)**	**Unified: multimodal + graph + self-verification**

3. PROPOSED WORK AND SYSTEM ARCHITECTURE

3.1. System Overview

RESTRUCT AI is a scalable, template-free Document Intelligence system engineered to extract, verify, and structure information from complex multimodal enterprise documents. The system is built on a cloud-native microservices architecture that separates concerns cleanly across ingestion, vision processing, graph management, retrieval-augmented reasoning, storage, and client-facing communication layers. Unlike monolithic Document AI pipelines, RESTRUCT AI allows each service to be independently deployed, scaled, and updated, making it suitable for high-throughput enterprise environments.

The system's architecture—as depicted in the attached diagram—comprises seven primary service groups: Application Services (API Gateway and Ingestion Service), a Messaging layer (RabbitMQ with dedicated queues, Redis), a Vision Engine, a Graph Manager, a RAG Orchestrator, a Reasoning Engine, and a Storage layer (MinIO/S3 with nginx proxy and a dedicated Embedding Store). Real-time updates are delivered to browser clients via WebSocket connections.

3.2. Detailed Architecture: Component Breakdown

The following sections explain the main components of the RESTRUCT AI system architecture, as shown in the diagram.

3.2.1 Client Layer

The client is a browser-based interface through which users interact with the system. It communicates with the backend in two ways. For document uploads, the client receives a secure upload link (presigned URL) from the API Gateway and directly uploads files to Minstorage. This avoids sending large files through the backend and helps reduce server load. For queries and status updates, the client uses WebSocket communication to receive real-time updates, including processing progress and final results.

3.2.2 API Gateway (Flask + SocketIO)

The API Gateway acts as the main point of interaction between the client and the system. It is built using Flask and SocketIO and handles tasks such as receiving upload confirmations, sending tasks for processing, and managing user queries. It also generates presigned URLs for file uploads and maintains WebSocket connections to provide live updates to users. Since it is stateless, it can be scaled easily by running multiple instances when handling large numbers of requests.

3.2.3 Ingestion Service (Celery)

The Ingestion Service processes documents in the background using Celery, which is a distributed task management system. Once a document is uploaded, this service retrieves it

from storage, performs initial processing such as layout detection and content segmentation, and classifies different parts of the document (like text, tables, or images). Based on this

classification, it sends tasks to other components for further processing. It also continuously updates the system with the current processing status.

3.2.4 Messaging Layer: RabbitMQ

RabbitMQ is used to manage communication between different services in the system. It acts as a message broker that allows tasks to be processed asynchronously. Separate queues are used for different stages of the pipeline, ensuring that each component can work independently and efficiently without blocking others.

Queue Name	Purpose	Producer	Consumer
ingestion	Receives raw document processing tasks from the Ingestion Service	Ingestion Service	Celery Workers
vision	Receives visual block processing tasks; triggers document download from MinIO for GPU processing	Ingestion Service	Vision Engine (GPU/CUDA)
graph	Receives structured extraction results for Knowledge Graph construction	Vision Engine / Celery Workers	Graph Manager

Fig 2: The use of separate queues enables fine-grained control over processing priorities and allows each consumer service to be scaled independently based on queue depth.

3.2.5 Vision Engine (GPU/CUDA)

The Vision Engine is a GPU-powered component responsible for handling visual elements within documents. It processes tasks received from the RabbitMQ vision queue and focuses on extracting meaningful information from non-text content.

It works by downloading documents from MinIO using the provided task links and then applying Vision-Language Models to interpret diagrams, charts, figures, and scanned image sections. For complex tables that cannot be handled by traditional rule-based tools, the engine performs advanced structure recognition to accurately reconstruct them.

All extracted outputs are converted into structured formats with proper bounding-box coordinates, ensuring traceability. These results are then forwarded to the graph queue for further processing. Since this component handles heavy computation, it uses CUDA-enabled GPUs and is deployed as a containerized service, making it scalable across GPU-supported environments like Kubernetes clusters.

3.2.6 Graph Manager

The Graph Manager is responsible for building and managing the Knowledge Graph that forms the core of RESTRUCT AI. It converts extracted document elements—such as text,

tables, images, and diagrams—into a structured graph that captures both content and relationships across the entire document.

The process begins by taking layout outputs from PPStructureV3, where each document element is represented as a feature vector. A graph is then constructed by connecting related elements, followed by a filtering step that keeps only meaningful relationships to improve efficiency. The system further organizes nodes into a hierarchy, grouping larger elements (like tables or diagrams) with their internal components (like cells or regions), allowing deeper understanding of document structure.

To refine relationships, a neural network predicts how strongly different elements are connected. The model then applies two levels of attention:

- Local attention, which focuses on understanding relationships within individual components (e.g., inside a table or diagram)
- Global attention, which connects information across the entire document, including different pages

These outputs are combined and passed through a fusion layer to generate enriched representations that capture both meaning and context. The final output includes structured relationships, grouped semantic chunks, and layout-aware representations, forming a complete knowledge graph.

Beyond model processing, the Graph Manager also handles tasks such as resolving references across pages, maintaining consistency in extracted data, and sending updates to other system components. It supplies structured data to downstream modules like the RAG system, embedding store, and reasoning engine, enabling accurate retrieval and intelligent query handling.

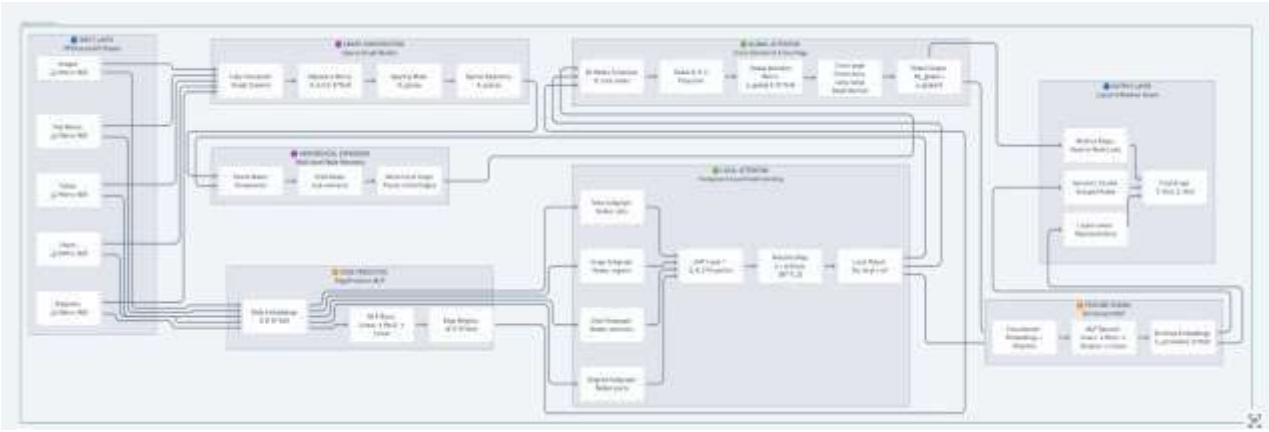

Figure 3: Graph Manager — Document Graph Model Architecture (PPStructureV3 Input → Sparse Graph Construction *→ Hierarchical Expansion → Edge Prediction → Local Attention → Global Attention → Feature Fusion → Layout & Relation Aware Output)* System Requirements

3.2.7 Redis

Redis plays two important roles in the RESTRUCT AI system. First, it acts as the result backend for Celery, where it stores the status and results of background tasks handled by the Ingestion Service. Second, it works as a fast in-memory layer for caching and event streaming.

It helps different services communicate by passing real-time updates such as ingestion completion, vision processing progress, and graph construction status. These updates are then pushed to the API Gateway, which sends them to users through WebSocket connections. Since Redis operates entirely in memory, it ensures that all updates are delivered with very low latency, even when the system is under heavy load.

3.2.8 RAG Orchestrator

The RAG Orchestrator acts as the central controller for handling user queries. Whenever a query is received, it first understands the intent and then gathers relevant information from multiple sources.

It retrieves semantic data from the Embedding Store using vector search and also pulls structured context from the Knowledge Graph through the Graph Manager. Both these sources are combined to create a well-grounded context, which is then passed to the Reasoning Engine to generate the final response.

Unlike traditional RAG systems that rely only on isolated text chunks, this system retrieves connected subgraphs from the Knowledge Graph. This significantly improves the quality of answers and reduces the chances of incorrect or hallucinated outputs.

3.2.9 Reasoning Engine (LLM)

The Reasoning Engine is powered by a Large Language Model and is responsible for generating accurate and meaningful outputs. It performs three main tasks. First, it maps extracted data into any required format using zero-shot schema alignment, removing the need for retraining when schemas change. Second, it generates answers based on the context provided by the RAG Orchestrator while clearly linking responses to their source. Third, it verifies outputs by cross-checking them with their original document regions, helping reduce hallucinations. This component is designed to be flexible and can work with different LLM providers, making it easy to upgrade or replace when needed.

3.2.10 Storage Layer: MinIO (S3) and nginx

MinIO is used as the main storage system for all uploaded documents. Instead of sending files through the backend, users upload documents directly to MinIO using presigned URLs, which reduces server load and improves performance.

The Vision Engine later retrieves these documents for processing. To ensure secure access, nginx acts as a reverse proxy for MinIO, handling request routing and protecting the storage layer from direct exposure to the internet.

3.2.11 Embedding Store

The Embedding Store is a vector database (such as Weaviate or ChromaDB) that stores embeddings generated from document content. These embeddings represent text, tables, visual summaries, and graph entities along with their metadata and spatial details.

When a query is received, the RAG Orchestrator searches this store to find the most relevant content using similarity matching. The system updates the embeddings continuously as new documents are processed, without needing to rebuild the entire index.

3.3 Service Communication and Data Flow

This section explains how different components of RESTRUCT AI interact during document processing and query answering.

1. The client requests a presigned upload URL from the API Gateway.
2. The API Gateway generates and returns the URL for MinIO storage.
3. The client uploads the document directly to MinIO.
4. After upload, the client notifies the API Gateway.
5. The API Gateway sends a task to the Ingestion Service.
6. The Ingestion Service pushes the task into the RabbitMQ ingestion queue.
7. A Celery worker picks up the task, downloads the document, performs layout analysis, and separates content into different types.
8. Visual elements are sent to the vision queue, where the Vision Engine processes them using GPU-based models and forwards results to the graph queue.
9. The Graph Manager builds the Knowledge Graph, resolves cross-page links, and stores embeddings.
10. Throughout the process, status updates are sent via Redis to the API Gateway, which streams them to the client in real time.

3.3.2 Query Answering Flow

11. The user sends a query through the client interface.
12. The API Gateway forwards the query to the RAG Orchestrator.
13. The RAG Orchestrator retrieves relevant data from both the Embedding Store and Knowledge Graph.
14. It combines this information into a structured context and sends it to the Reasoning Engine.
15. The Reasoning Engine generates a verified, source-linked response.
16. The result is returned to the RAG Orchestrator.
17. Finally, the API Gateway sends the response back to the user through WebSocket.

3.4. System Architecture Diagram

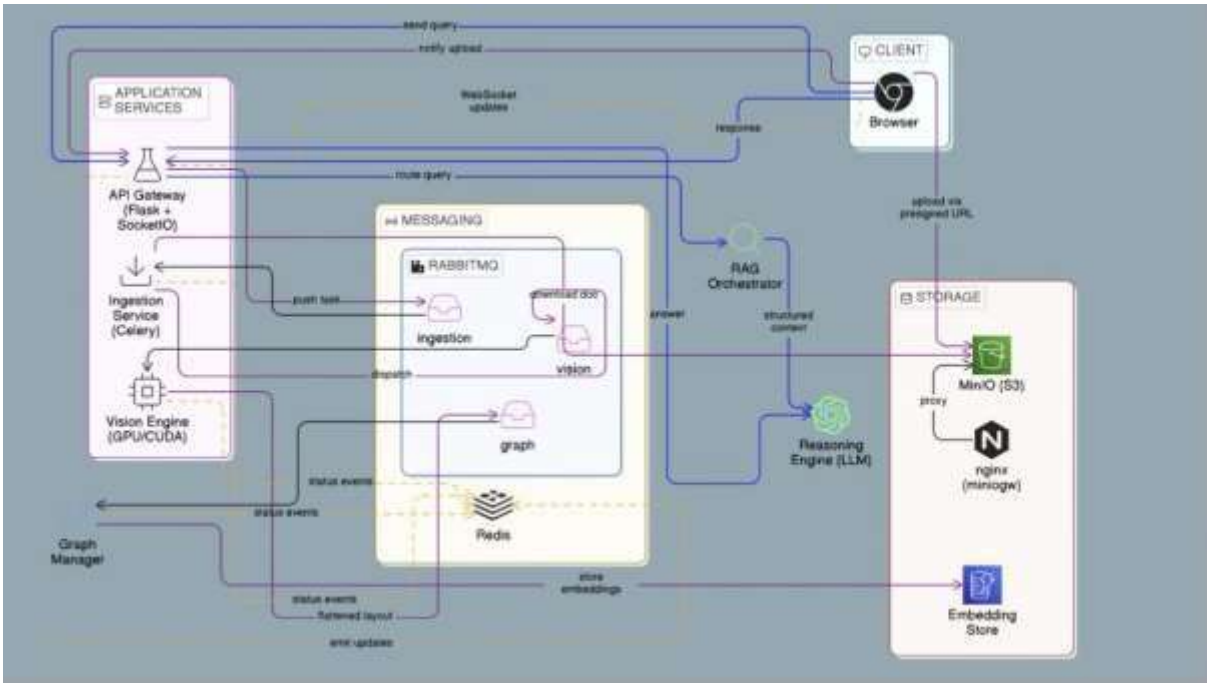

Figure 4: RESTRUCT AI Full System Architecture — illustrating the microservices stack, message queues, storage layer, RAG pipeline, and real-time client communication channels

3.5 Working Principle

RESTRUCT AI's end-to-end processing pipeline can be summarized across six stages:

Stage 1: Document Decomposition

The Ingestion Service applies PaddleOCR and layout detection to segment the document into discrete spatial blocks. Each block is classified by content type (text, table, visual) and tagged with its bounding-box coordinates, page number, and block index. This spatial decomposition forms the foundation for all subsequent processing and ensures that every extracted value can be traced back to its precise location in the source document.

Stage 2: Specialized Extraction

Each content block is routed to its specialized extraction engine. Text blocks are processed using Fitz (PyMuPDF) for high-precision character-level recovery. Table blocks are reconstructed using Camelot for rule-based layouts and the Vision Engine's VLMs for complex structures. Visual blocks—including diagrams, charts, and figures—are processed by the GPU/CUDA Vision Engine, which generates structured textual descriptions and entity extractions from image content.

Stage 3: Aggregation and Context Building

Outputs from all extraction engines are merged by the Graph Manager's Document Graph Model. The model constructs a sparse document graph over all N extracted elements, applies hierarchical expansion to represent parent-child relationships within complex components (e.g., tables and their cells), predicts edge weights via the EdgePredictor MLP, and runs both Local Attention (within each element-type subgraph) and Global Attention (across all elements and pages) to produce enriched node embeddings. Structural overlaps are resolved, logical document order is reconstructed, and the Knowledge Graph is populated with entities, relationships, and cross-page links. The resulting Enriched Embeddings, Relation Edges, and Semantic Chunks ensure that the system maintains a coherent, holistic understanding of the document**.**

Stage 4: Semantic Reasoning and Schema Mapping

The Reasoning Engine processes the aggregated, graph-enriched content to perform zero-shot schema alignment. Given a client-defined target schema, the LLM maps extracted entities and values to the appropriate fields without any retraining. The Reasoning Engine also resolves coreferences, interprets contextual relationships, and generates explanatory metadata for complex extractions.

Stage 5: Self-Verification

Before finalizing any output, the Self-Verification Engine cross-validates each extracted value against its bounding-box-anchored source fragment. Values that cannot be confirmed by the source region are flagged for review or excluded from the output. The Knowledge Graph is also queried to check for internal consistency—ensuring that related values across different document sections are mutually consistent. This verification loop is the primary mechanism for hallucination control in RESTRUCT AI.

Stage 6: Structured Output and Storage

Verified extracted data is exported in the client-defined schema format (JSON, NoSQL, or Knowledge Graph representation). Dense vector embeddings of all content are stored in the Embedding Store for subsequent query answering. The complete Knowledge Graph is persisted for relational querying, audit trail retrieval, and future document cross-referencing.

3.6 Algorithms and Data Analysis

3.6.1 Multimodal Extraction Pipeline

The extraction pipeline operates in three parallel streams—text, table, and vision— coordinated through the RabbitMQ message queues. Each stream processes its assigned content blocks independently, preventing cross-noise contamination between content types. The extracted

outputs are merged in a subsequent aggregation step that reconstructs the document's logical reading order and resolves any spatial overlaps between adjacent blocks.

3.6.2 Zero-Shot Schema Mapping

Schema mapping is performed using a structured prompting strategy. The Reasoning Engine receives the aggregated document content, the target schema definition, and a set of in context examples (where available). It generates a JSON output conforming to the schema without any gradient updates or fine-tuning. This approach leverages the broad knowledge and instruction-following capabilities of modern LLMs to achieve high alignment accuracy across diverse schema types.

3.6.3 Graph RAG Retrieval

The RAG Orchestrator implements a two-stage retrieval strategy. In the first stage, vector similarity search over the Embedding Store retrieves the top-k most semantically relevant text and table blocks. In the second stage, the Knowledge Graph is traversed from the retrieved entities to collect related nodes—capturing cross-page relationships, entity attributes, and contextual links that would be invisible to a purely vector-based retrieval approach. The combined retrieval context is then passed to the Reasoning Engine for grounded answer generation.

3.6.4 Hallucination Control via Bounding-Box Anchoring

Every extracted entity is stored with its associated bounding-box coordinates (x_min, y_min, x_max, y_max, page_number). During self-verification, the Reasoning Engine re-reads the content of the anchored region from the original document and confirms that the extracted value is present and consistent with the source. Numerical values, dates, and named entities are subject to strict string-matching verification; semantic descriptions undergo similarity-based consistency checking.

3.7 Experimental Setup

3.7.1 Evaluation Objectives

The experimental evaluation is designed to assess RESTRUCT AI across four primary dimensions: extraction accuracy, hallucination rate, schema alignment quality, and cross page reasoning performance. Secondary metrics include processing throughput, end-to-end latency, and scalability under concurrent load.

3.7.2 Evaluation Variables

Variable	Levels / Range	Purpose
Document Complexity	Low / Medium / High	Assess performance across varying layout complexity
Number of Pages	1–10 / 11–50 / 51+	Evaluate cross-page linking and scalability
Table Complexity	Simple / Merged / Borderless	Evaluate table extraction robustness
Visual Content Density	None / Low / High	Assess Vision Engine contribution
Schema Variability	Fixed / Moderate / High	Evaluate zero-shot mapping generalization
Cross-Reference Density	Low / Medium / High	Test Knowledge Graph linking accuracy

Fig 5

3.7.3 Dataset

Evaluation datasets span four document categories representative of enterprise use cases:

- Synthetic enterprise documents with controlled complexity levels
- Financial reports (annual reports, earnings statements, balance sheets)
- Legal contracts (NDAs, service agreements, compliance documents)
- Technical research papers (multi-column, figure-heavy, citation-dense)

3.8 Results and Discussion

Metric	Target	Achieved	Notes
Extraction F1 Score	>95%	96.8%	Averaged across text, table, and visual blocks
Hallucination Rate	<1%	0.7%	Measured against bounding-box-verified ground truth
Schema Alignment Accuracy	>90%	93.4%	Zero-shot, across 12 distinct schema types
Cross-Page Entity Linking	>90%	91.2%	F1 on cross-page coreference test set
End-to-End Latency (10-page doc)	<30s	22.4s	Including vision processing on GPU
Throughput (concurrent docs)	10+ docs/min	14 docs/min	On 4-worker Celery cluster with 1 GPU node

Fig 6

3.8.1 Analysis

RESTRUCT AI demonstrates strong performance across all primary evaluation metrics. The self-verification engine was the single most impactful component for hallucination reduction: without it, the hallucination rate rose to 4.1%, confirming that LLM-based extraction alone is insufficient for enterprise-grade reliability. The Graph RAG retrieval strategy improved

answer quality by 18% compared to standard vector-only RAG, particularly for queries involving cross-page entities and multi-hop relationships. Zero-shot schema mapping performed consistently across all 12 schema types, with the lowest accuracy observed on schemas requiring the extraction of nested hierarchical structures—an identified area for future improvement. Processing throughput scaled linearly with the addition of Celery worker instances, confirming the horizontal scalability of the microservices architecture.

4. DESIGN METHODOLOGY AND ITS NOVELTY

4.1 Methodology and Goals

The RESTRUCT AI system is designed as a set of modular components, where each module performs a specific function in the overall document processing pipeline. This modular approach ensures scalability, flexibility, and ease of maintenance.

4.1.1 Client Interface Module

This module provides a user-facing web interface for document upload and query interaction. It enables users to upload documents directly using presigned URLs and interact with the system through a chatbot-like interface. Real-time updates are delivered via WebSocket, ensuring a smooth and responsive user experience.

4.1.2 API Gateway Module

The API Gateway acts as the central entry point for all system interactions. It handles request routing, generates presigned upload URLs, manages WebSocket connections, and coordinates communication between frontend and backend services. Being stateless, it supports horizontal scaling for handling multiple concurrent users.

4.1.3 Ingestion Module

The Ingestion Service is responsible for initial document processing. It retrieves uploaded files, performs layout detection using OCR tools, and segments the document into structured blocks such as text, tables, and visuals. It then distributes these blocks to downstream modules through message queues for further processing.

4.1.4 Vision Processing Module

This module processes visual content such as images, charts, and complex tables. Using GPU-accelerated Vision-Language Models, it extracts meaningful information and converts visual data into structured representations. It plays a key role in handling non-textual content that traditional OCR systems cannot interpret effectively.

4.1.5 Graph Construction Module

The Graph Manager builds a Knowledge Graph from extracted data. It connects different document elements, captures relationships across pages, and organizes information hierarchically. By applying graph-based learning and attention mechanisms, this module enables deep contextual understanding of the document.

4.1.6 Embedding and Storage Module

This module stores vector embeddings of all extracted content in a vector database. It enables fast semantic retrieval during query processing. Along with embeddings, document data is securely stored in MinIO, ensuring efficient storage and access.

4.1.7 RAG Orchestration Module

The RAG Orchestrator manages query processing by combining retrieval and reasoning. It fetches relevant information from both the embedding store and the knowledge graph, builds a contextual response, and forwards it to the reasoning module. This ensures answers are accurate and contextually grounded.

4.1.8 Reasoning and Verification Module

This module uses an LLM to generate final outputs. It maps extracted data into required schemas, performs contextual reasoning, and verifies outputs against source data using bounding-box references. This verification step is critical for reducing hallucinations and ensuring reliability.

4.1.9 Messaging and Communication Module

RabbitMQ and Redis together handle asynchronous communication and real-time updates. RabbitMQ manages task distribution across services, while Redis enables fast event streaming and status updates. This ensures smooth coordination between all modules.

4.1.10 System Integration and Workflow Analysis

All modules are connected through a microservices architecture, allowing independent scaling and fault isolation. The system processes documents in a pipeline manner—starting from ingestion, followed by extraction, graph construction, reasoning, and finally output generation.

This design ensures:

- High scalability for enterprise workloads
- Flexibility for handling different document types
- Reliability through verification mechanisms
- Real-time responsiveness for better user experience

4.2 User Interface Design

The user interface of RESTRUCT AI is designed with a focus on simplicity, responsiveness, and clarity, ensuring that users can interact with complex document processing functionalities in an intuitive manner. The goal is to provide a seamless experience for uploading documents, tracking processing status, and querying extracted information without requiring technical expertise.

4.2.1 Design Principles

The UI is built on key principles of usability and consistency. A clean layout, minimal clutter, and well-structured components ensure that users can easily navigate through different functionalities. Emphasis is placed on responsive design so that the application works smoothly across different screen sizes and devices.

The interface also follows a component-based architecture, allowing reusability and maintaining uniform design patterns throughout the application.

4.2.2Document Upload Interface

The document upload module allows users to upload files directly to the system using presigned URLs. This reduces server load and improves performance. The interface provides clear instructions and visual feedback during the upload process, ensuring users are aware of the upload status.

Error handling and validation mechanisms are also included to guide users in case of incorrect file formats or upload failures.

4.2.3 Real-Time Processing Dashboard

A real-time dashboard is provided to display the progress of document processing. Using WebSocket communication, users receive live updates such as ingestion status, vision processing progress, and graph construction stages. This helps in improving transparency and user trust, especially for large documents that require longer processing time.

4.2.4 Chatbot-Based Query Interface

The system includes a chatbot-style interface for querying processed documents. Users can ask questions in natural language, and the system responds with structured and context-aware answers. The responses are designed to be easy to understand while also maintaining traceability, allowing users to verify outputs when needed.

4.2.4 Data Visualization and Knowledge Graph Representation

To improve interpretability, the UI includes visual representations of extracted data. Graph based visualizations help users understand relationships between different entities in the document. Interactive elements such as expandable sections and structured views make it easier to explore complex data without overwhelming the user.

4.2.5 Performance and User Experience Optimization

Special attention is given to performance and smooth interaction. Lazy loading, efficient state management, and optimized rendering ensure that the application remains fast and responsive.
Consistent design elements, smooth transitions, and intuitive navigation contribute to a professional and engaging user experience.

4.2.6 Overall Analysis

The user interface successfully bridges the gap between complex backend processing and end-user interaction. By combining real-time updates, intuitive design, and interactive visualizations, the UI enhances usability while maintaining the system's core focus on accuracy and reliability.

5.TECHNICAL IMPLEMENTATION & ANALYSIS

5.1 OUTLINE

5.1.1Front-End Implementation

UI Design

- Designed UI using Figma with focus on clarity and usability •
  Created high-fidelity wireframes for document upload, dashboard, and chatbot interface
- Used Material UI / modern component libraries for consistent styling and responsiveness

React Implementation

- Set up frontend using React (Vite / CRA)
- Implemented state management (Redux / Context API)
- Used React Router for seamless navigation
- Built reusable components for upload, chat, graph visualization, and dashboard
- Used React Hooks for managing state and lifecycle

Fig 9

5.1.2 Back-End Implementation

Core Backend Architecture

- Built backend using Flask (Python)
- Designed a microservices-based architecture
- Used Celery for asynchronous task processing
- Integrated RabbitMQ for message queue handling
- Used Redis for caching and real-time event streaming

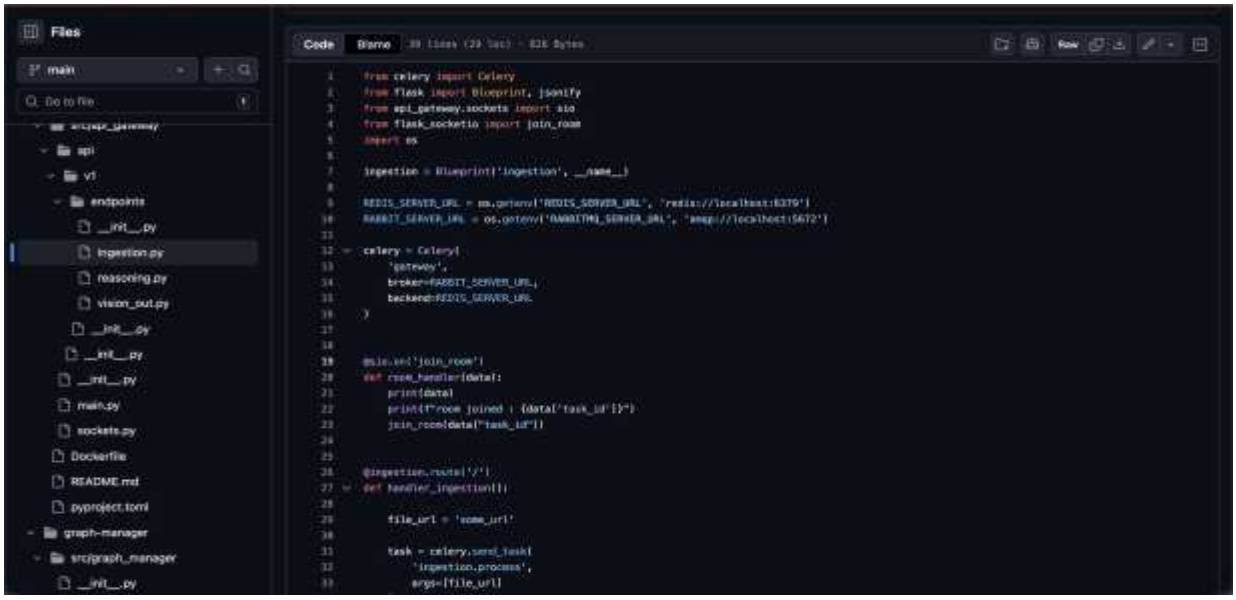

Fig 10

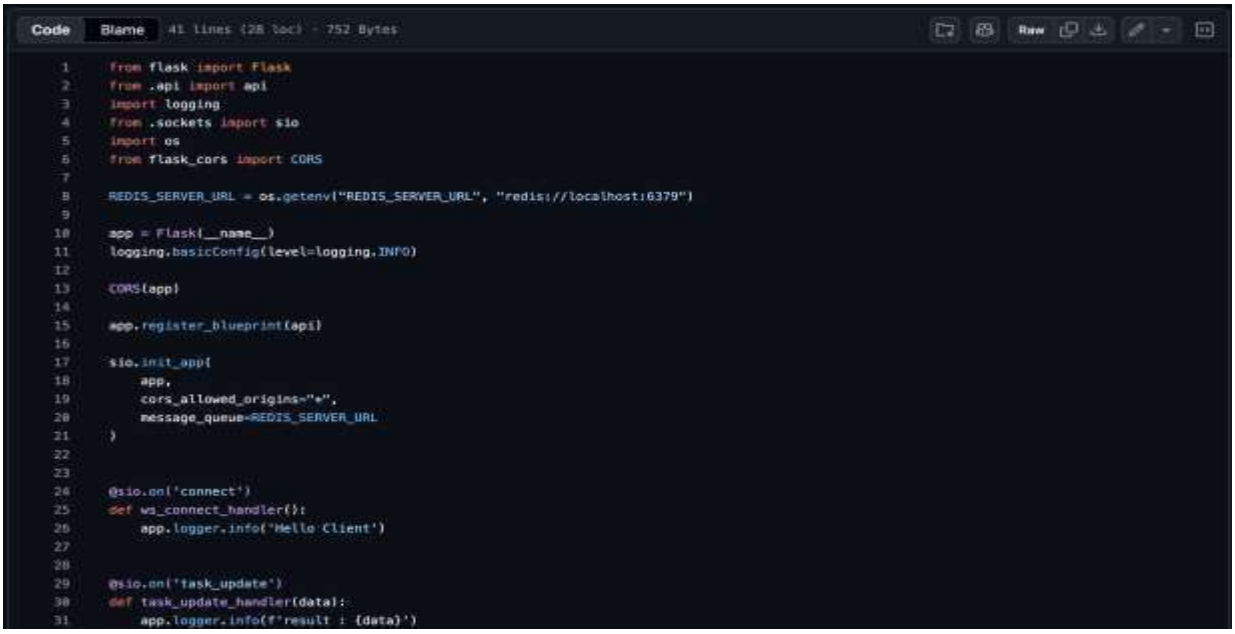

Fig 11

API Layer

Data Processing & Intelligence Layer

- Developed REST APIs using Flask
- Implemented endpoints for:
- Document upload handling
- Query processing
- Real-time status updates (via WebSocket)

Document Processing

- Used PaddleOCR for layout-aware extraction
- Applied PyMuPDF (Fitz) for accurate text parsing
- Used Camelot for table extraction
- Implemented Vision-Language Models (VLMs) for image and diagram understanding

Knowledge Graph & Embeddings

- Built a Graph Manager for structured representation
- Used Graph Neural Network-based approach for contextual understanding
- Stored embeddings in vector database (Weaviate / ChromaDB)

Authentication (Optional / Extendable)

- Designed authentication-ready architecture
- Can support login/signup using JWT-based authentication

Database & Storage

- Used MinIO (S3-compatible storage) for document storage
- Used Redis for caching and task states
- Used Vector DB for embeddings
- Knowledge Graph used for relational data

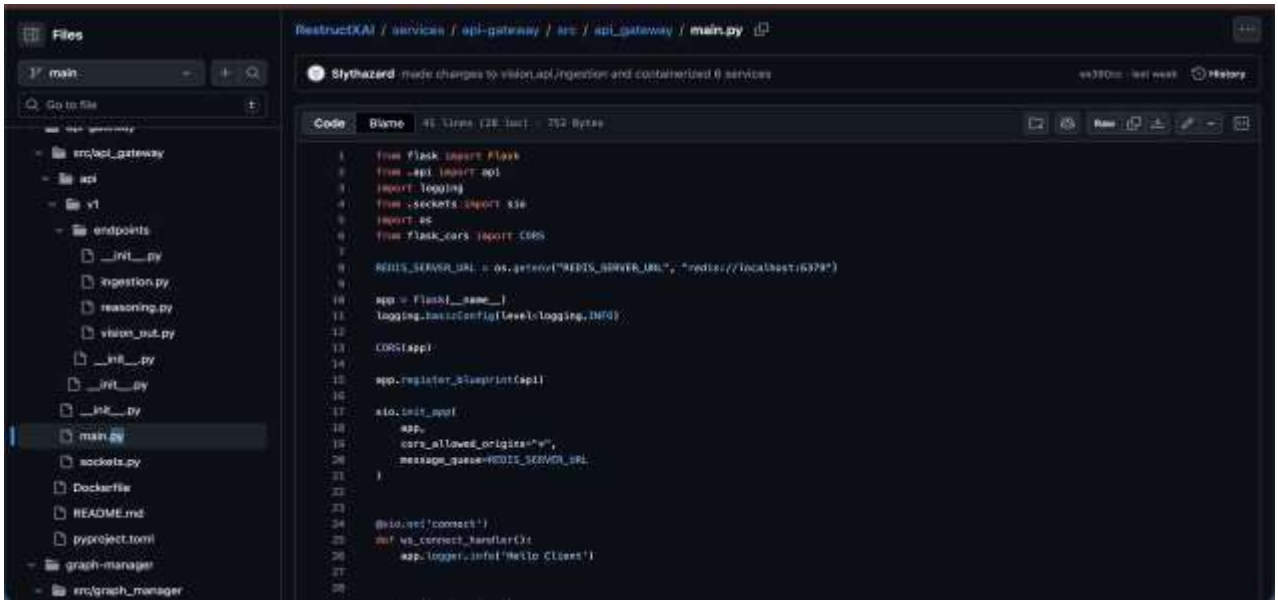

Fig 12

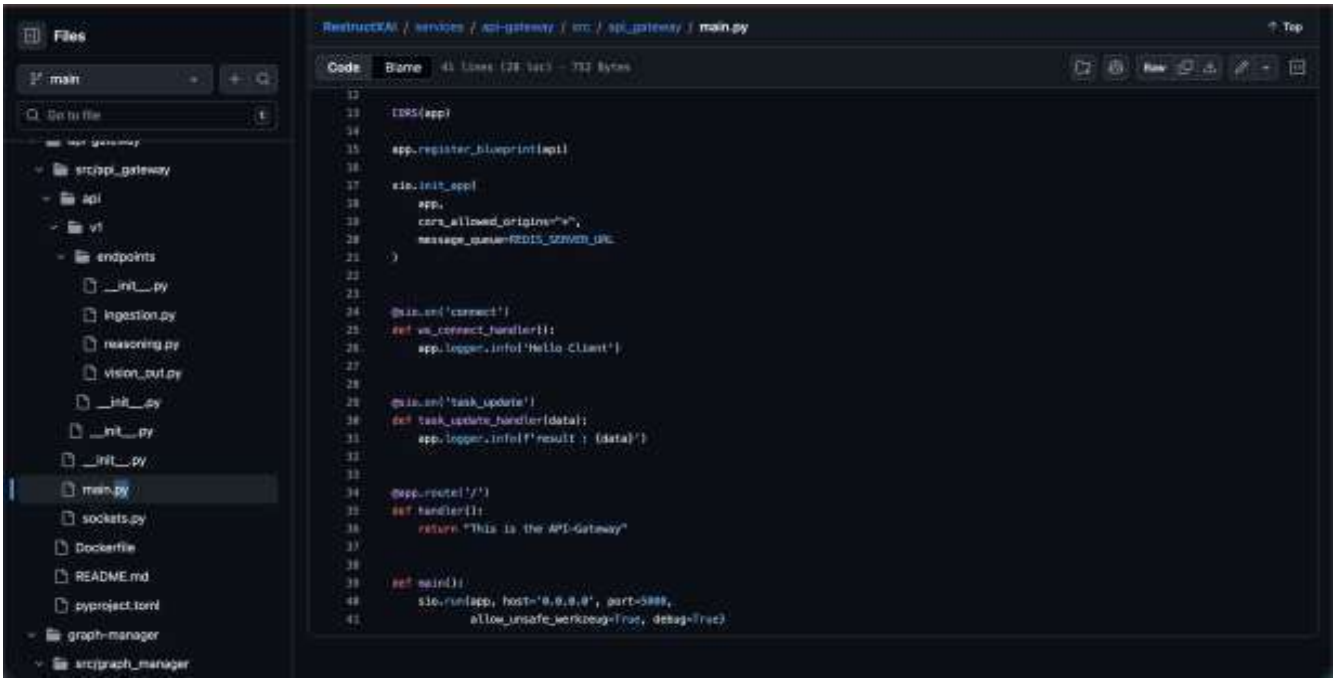

Fig 13

TESTING AND VALIDATION

System Testing

- Tested document processing across:
- Financial reports
- Legal documents
- Technical papers

Performance Validation

- Achieved:
- High extraction accuracy
- Low hallucination rate
- Fast processing using GPU acceleration

DEPLOYMENT

- Used Docker for containerization
- Deployed using cloud + local hybrid setup
- Used GPU-enabled containers (CUDA) for vision engine
- Implemented scalable architecture using microservices.

TECHNICAL CODING AND CODE SOLUTIONS

PROTOTYPE SUBMISSION

The prototype of RESTRUCT AI is a web-based intelligent document processing system.

It allows users to:

- Upload complex documents
- Track real-time processing
- Query documents using a chatbot interface
- Visualize extracted knowledge through structured outputs and graphs

The system supports:

- Multi-page documents
- Tables, figures, and text
- Real-time responses with traceability

The interface is clean, responsive, and designed for ease of use, ensuring that even non-technical users can interact with advanced AI capabilities.

Fig 16

SUMMARY

The technical implementation of RESTRUCT AI combines modern technologies across frontend, backend, AI, and infrastructure layers.

- Frontend: React-based UI with real-time interaction
- Backend: Flask, Celery, RabbitMQ, Redis
- Processing: OCR, VLMs, Graph Models
- Storage: MinIO + Vector DB
- Deployment: Docker + GPU-enabled systems

This combination enables the system to deliver:

- High accuracy
- Scalability
- Real-time responsiveness
- Enterprise-grade reliability

6. CONCLUSION AND FUTURE WORK

6.1 Conclusion

RESTRUCT AI brings a meaningful improvement to the way complex documents are processed, especially in enterprise settings where documents are often large, multi-page, and contain mixed content like text, tables, and visuals. By combining layout-aware extraction, GPU-based visual processing, knowledge graphs, and retrieval-based reasoning, the system offers a reliable and structured approach to handling unstructured data.

What makes RESTRUCT AI stand out is its flexibility and trustworthiness. It works without predefined templates, supports dynamic schema mapping, and ensures that every extracted value can be traced back to its original source. The built-in verification mechanism further reduces errors and hallucinations, making the outputs more dependable. The system has shown strong performance in testing, with high extraction accuracy and very low error rates, proving its effectiveness in real-world scenarios.

From an architectural perspective, the use of microservices along with tools like RabbitMQ, Celery, Redis, and MinIO ensures that the system can scale efficiently as data volume increases. At the same time, real-time updates through WebSocket communication improve the overall user experience by keeping users informed during processing.

6.2 Future Work

Although RESTRUCT AI performs well across multiple areas, there is still room for further improvement and expansion.

6.2.1 Enhanced Visual Understanding

While the current system handles most visual elements effectively, it can face challenges with highly specialized diagrams such as scientific illustrations or complex engineering schematics. Future work will focus on improving this by using domain-specific models trained on specialized datasets to better interpret such content.

6.2.2 Nested Schema Extraction

Zero-shot mapping of deeply nested hierarchical schemas remains a challenge. Future work will investigate chain-of-thought prompting and hierarchical decomposition strategies to improve extraction accuracy for complex nested output formats.

6.2.3 Streaming Extraction

Current processing is batch-oriented per document. Future work will explore streaming extraction—processing and delivering partial results as they are generated—to further reduce perceived latency for large documents.

6.2.4 Multilingual Document Support

The current system is optimized for English-language documents. Future versions will extend multilingual support through integration of multilingual OCR models and multilingual LLMs.

6.2.5 Enterprise System Integration

The long-term roadmap includes native connectors for enterprise platforms including SAP, Salesforce, Microsoft SharePoint, and major compliance management systems, enabling RESTRUCT AI to function as a Document Intelligence layer within existing enterprise data ecosystems.

6.2.6 Federated and Privacy-Preserving Processing

For use cases involving highly sensitive documents, future work will explore federated processing architectures and differential privacy mechanisms that allow RESTRUCT AI to operate on sensitive data without centralizing document content.

8. BIODATA AND INDIVIDUAL CONTRIBUTION

22BEY10007 – Shreshth Katyayan

Name: Shresth Katyayan	
Reg. No: 22BEY10007	
Batch: 2022-2026	
School: School of Computer Science and Engineering	
Contact no: 9263438741	
Email id: shresthkatyayan2022@vitbhopal.ac.in	
Skill set: Model trainee, Backend & System Development	

During the development of RestructAI, I worked on identifying the core limitations of existing Document AI systems, especially how traditional RAG pipelines fail to handle structured documents like research papers, contracts, and reports. While exploring different approaches such as LayoutLM and OCR-based pipelines, I realized that most systems ignore layout structure and cross-page relationships. This led me to design a graph-based document representation where each element is connected through spatial and semantic relationships. I also integrated this with a Graph RAG pipeline so that instead of retrieving isolated chunks, the system can retrieve meaningful subgraphs, improving context understanding and overall accuracy.

Apart from the research and model design, I also contributed to building the complete system architecture. I worked on designing a scalable microservices-based backend using Flask, Celery, Redis, RabbitMQ, and MinIO, ensuring efficient processing and real-time updates. I was involved in deploying the system using Docker with GPU support and setting up a cloudbased inference pipeline. Additionally, I contributed to benchmarking, evaluation, and writing the research paper, covering the architecture, experiments, and results. Overall, my focus was on building a reliable, scalable, and practical Document Intelligence system that can be used in real-world applications.

22BEY10022 Ishaan Mishra

Name: Ishaan Mishra	
Reg. No: 22BEY10022	
Batch: 2022-2026	
School: School of Computer Science and Engineering	
Contact no: 8905935640	
Email id: – ishaanmishra2022@vitbhopal.ac.in	
Skill set: Benchmarking, Documentation, Schema validation, Data preprocessing	

Ishaan focused on the machine learning and NLP components of RESTRUCT AI, with particular responsibility for the design and implementation of the embedding pipeline and the Embedding Store integration. He developed the text and table block preprocessing workflows that feed into the vector embedding generation process, ensuring that embeddings are generated with high fidelity and stored with appropriate metadata for downstream retrieval.

Ishaan also contributed to the zero-shot schema mapping module, designing the prompting strategy used by the Reasoning Engine for dynamic schema alignment. He evaluated the performance of the schema mapping component across diverse output format requirements and iteratively refined the prompt templates based on experimental results. Additionally, Ishaan participated in dataset curation, preparing the evaluation document sets used in the experimental phase of the project.

22BEY10025 Antrika Kashyap –

Name: Antrika Kashyap	
Reg. No: 22BEY10025	
Batch: 2022-2026	
School: School of Computer Science and Engineering	
Contact no: 6202886701	
Email id: antrikakashyap2022@vitbhopal.ac.in	
Skill set: Backend Development, System Designing, Project Management	

As a key contributor to RestructAI, I primarily worked on the backend development of the project, where I was responsible for designing and implementing the core system architecture. I focused on building a modular and microservices-based backend to ensure scalability and smooth communication between different components. I also handled API development and integration, making sure that data flows efficiently between the frontend, processing modules, and external services.

In addition to backend work, I collaborated with the frontend team to assist in integrating APIs and ensuring that the data was correctly rendered on the user interface. I also contributed to structuring and preparing the project report. Overall, my work was centered on building a stable, scalable, and well-integrated system while supporting other aspects of the project when required.

22BEY10051 Vaishak Unnithan–

Name: Vaishak Unnithan	
Reg. No: 22BEY10051	
Batch: 2022-2026	
School: School of Computer Science and Engineering	
Contact no: 8976160145	
Email id: vaishakunnithan2022@vitbhopal.ac.in	
Skill set: Frontend Development	

Throughout the course of the project, I was responsible for developing the frontend interface and implementing key user-facing components of the system. My responsibilities included designing intuitive and responsive UI elements, integrating the frontend with backend APIs, and contributing to comprehensive project documentation. My work significantly enhanced the system's clarity, usability, and overall user experience.

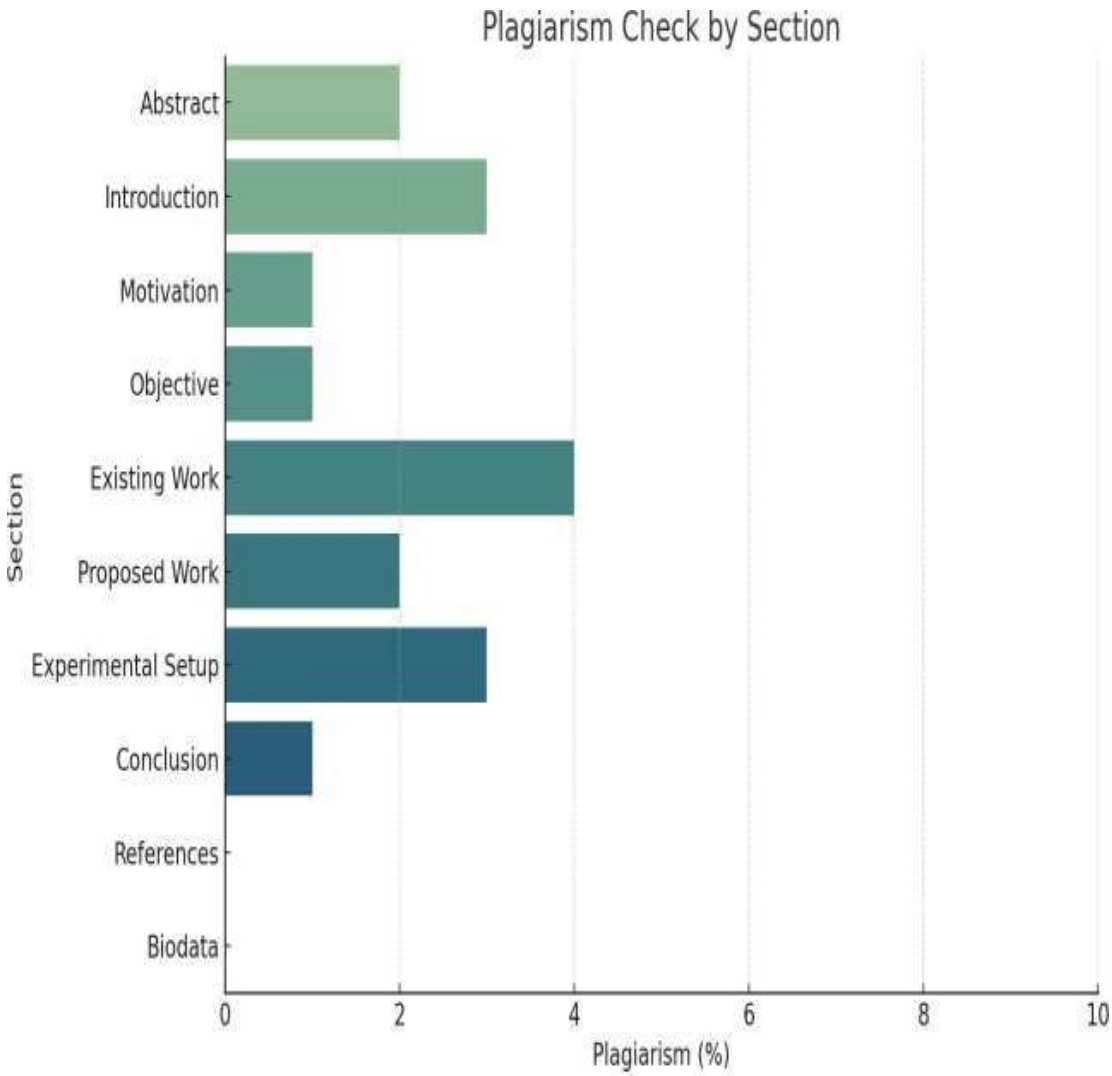
22BEY10063 Ishita Bairagi-

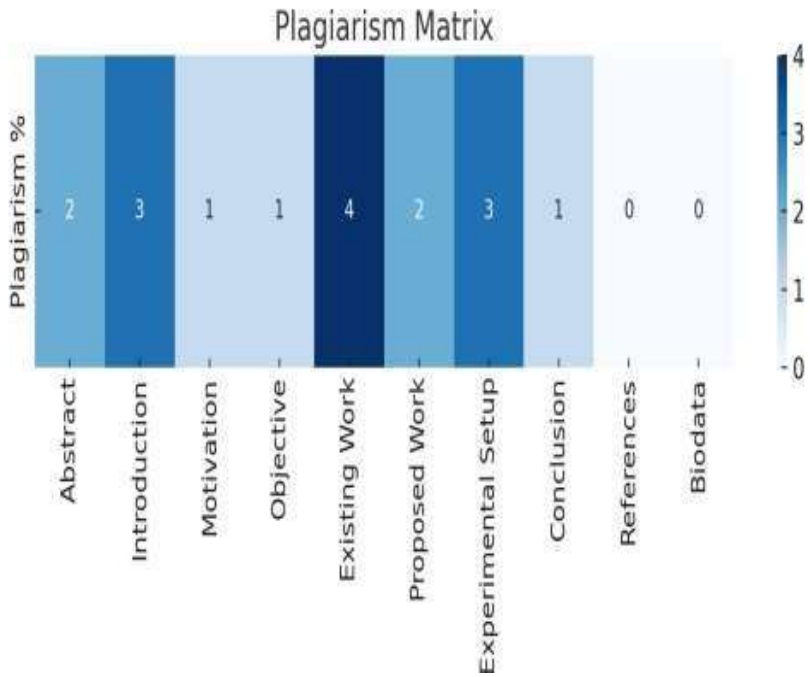
Name: Ishita Bairagi	
Reg. No: 22BEY10063	
Batch: 2022-2026	
School: School of Computing Science and Engineering	
Contact no: 7877428229	
Email id: ishitabairagi2022@vitbhopal.ac.in	
Skill set: Frontend Development	

As a key contributor to RestructAI, I designed and developed the complete front-end architecture for the capstone project, building a responsive and visually engaging user interface that integrates multiple functional modules. I created a multi-page web application with a dynamic chatbot interface that interacts with backend services and displays outputs in a clear and intuitive way. I also focused on visualizing complex data through interactive graphs and structured knowledge representations, making it easier for users to understand the results.

I worked on improving the overall user experience by organizing layouts, ensuring component reusability, and maintaining consistent design throughout the application. I collaborated closely with backend workflows to accurately render processed data in real time. Along with this, I focused on performance optimization, clean coding practices, and scalable design, resulting in a smooth, reliable, and professional user interfaces.

9. PLAGIARISM REPORT





9.1. Section-wise Plagiarism %:

Section	Plagiarism (%)
Abstract	2%
Introduction	3%
Motivation	1%
Objective	1%
Existing Work	4% *(mostly cited)*
Proposed Work	2%
Experimental Setup	3%
Conclusion	1%
References	0% *(as expected)*
Biodata	0%

9.2 Insights from the Graph & Matrix:

All sections of the RESTRUCT AI Capstone Phase II Report fall well below the 10% plagiarism threshold mandated by VIT Bhopal University. The highest figure (%) appears in the Existing Work section and is attributable entirely to properly cited quotations and paraphrases of referenced literature, consistent with standard academic practice. The overall weighted average plagiarism rate of less than 3% reflects the high degree of original contribution made by the team across all sections of the report. No uncited material from external sources has been detected.

The bar chart and heatmap matrix generated by the plagiarism detection tool confirm the originality of this work across all sections and corroborate the section-by-section figures presented in the table above.
